Which hyperplane?

Which hyperplane?

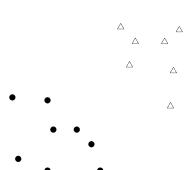

- For linearly separable training sets: there are infinitely many separating hyperplanes.
- They all separate the training set perfectly . . .
- ...but they behave differently on test data.
- Error rates on new data are low for some, high for others.
- How do we find a low-error separator?

- Machine-learning research in the last two decades has improved classifier effectiveness.
- New generation of state-of-the-art classifiers: support vector machines (SVMs), boosted decision trees, regularized logistic regression, neural networks, and random forests
- Applications to IR problems, particularly text classification

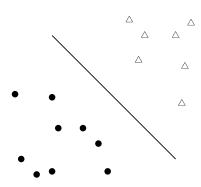

SVMs: A kind of large-margin classifier

Vector space based machine-learning method aiming to find a decision boundary between two classes that is maximally far from any point in the training data (possibly discounting some points as outliers or noise)

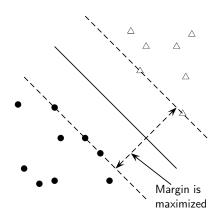

• 2-class training data

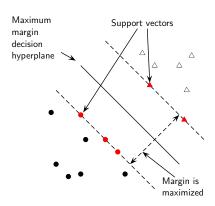

- 2-class training data
- decision boundary → linear separator

- 2-class training data
- decision boundary → linear separator
- criterion: being maximally far away from any data point \rightarrow determines classifier margin

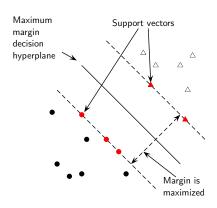

- 2-class training data
- decision boundary → linear separator
- criterion: being maximally far away from any data point \rightarrow determines classifier margin
- linear separator position defined by support vectors

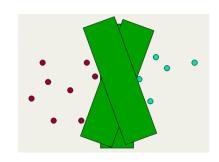

Why maximize the margin?

- Points near decision surface → uncertain classification decisions
- A classifier with a large margin is always confident
- Gives classification safety margin (measurement or variation)

Why maximize the margin?

- SVM classifier: large margin around decision boundary
- compare to decision hyperplane: place fat separator between classes
 - unique solution
- decreased memory capacity
- increased ability to correctly generalize to test data

Equation

Equation of a hyperplane

$$\vec{w} \cdot x_i + b = 0 \tag{1}$$

Distance of a point to hyperplane

$$\frac{|\vec{w} \cdot x_i + b|}{||\vec{w}||} \tag{2}$$

• The margin ρ is given by

$$\rho \equiv \min_{(x,y)\in\mathcal{S}} \frac{|\vec{w} \cdot x_i + b|}{||\vec{w}||} = \frac{1}{||\vec{w}||}$$
(3)

Equation

Equation of a hyperplane

$$\vec{w} \cdot x_i + b = 0 \tag{1}$$

Distance of a point to hyperplane

$$\frac{|\vec{w} \cdot x_i + b|}{||\vec{w}||} \tag{2}$$

• The margin ρ is given by

$$\rho \equiv \min_{(x,y)\in\mathcal{S}} \frac{|\vec{w} \cdot x_i + b|}{||\vec{w}||} = \frac{1}{||\vec{w}||}$$
(3)

• This is because for any point on the marginal hyperplane, $\vec{w} \cdot x + b = \pm 1$

Optimization Problem

We want to find a weight vector \vec{w} and bias b that optimize

$$\min_{\vec{w},b} \frac{1}{2} ||w||^2 \tag{4}$$

subject to $y_i(\vec{w} \cdot x_i + b) \ge 1$, $\forall i \in [1, m]$.
